

## CS 32 Worksheet 3

This worksheet is entirely **optional**, and meant for extra practice. Some problems will be more challenging than others and are designed to have you apply your knowledge beyond the examples presented in lecture, discussion or projects. All exams will be done on paper, so it is in your best interest to practice these problems by hand and not rely on a compiler.

### Concepts

#### Recursion

### Problems

1. What does the following code output and what does the function `LA_power` do?

```
#include <iostream>
using namespace std;

int LA_power(int a, int b)
{
    if (b == 0)
        return 0;
    if (b % 2 == 0)
        return LA_power(a+a, b/2);

    return LA_power(a+a, b/2) + a;
}

int main()
{
    cout << LA_power(3, 4) << endl;
}
```

2. Given a singly-linked list class `LL` with a member variable *head* that points to the first *Node* struct in the list, write a function to recursively delete the whole list. Assume each *Node* object has a next pointer.

```
void LL::deleteList()
```

3. Implement a recursive function that returns the maximum value in an array of size `n`. You may assume that `n` will be at least 1. The header of the function is given: `int fun(int a[],int n)`

4. Given a string *str*, recursively compute a new string such that all the 'x' chars have been moved to the end.

```
string endX(string str);
```

Example:

```
endX("xrxe") → "rexx"
```

5. Implement the following function in a recursive fashion:

```
bool isSolvable(int x, int y, int c);
```

This function should return true if there exists nonnegative integers *a* and *b* such that the equation  $ax + by = c$  holds true. It should return false otherwise.

```
Ex: isSolvable(7, 5, 45) == true //a == 5 and b == 2
```

```
Ex: isSolvable(1, 3, 40) == true //a == 40 and b == 0
```

```
Ex: isSolvable(9, 23, 112) == false
```

6. A robot you have programmed is attempting to climb a flight of stairs, for which each step has an associated number. This number represents the size of a leap that the robot is allowed to take backwards or forwards from that step (the robot, due to your engineering prowess, has the capability of leaping arbitrarily far). The robot must leap this exact number of steps.

Unfortunately, some of the steps are traps, and are associated with the number 0; if the robot lands on these steps, it can no longer progress. Instead of directly attempting to reach the end of the stairs, the robot has decided to first determine if the stairs are climbable. It wishes to achieve this with the following function:

```
bool isClimbable(int stairs[], int length);
```

This function takes as input an array of int that represents the stairs (the robot starts at position 0), as well as the length of the array. It should return true if a path exists for the robot to reach the end of the stairs, and false otherwise.

```
Ex: isClimbable({2, 0, 3, 0, 0}, 5) == true
```

```
    //stairs[0]->stairs[2]->End
```

```
Ex: isClimbable({1, 2, 4, 1, 0, 0}, 6) == true
```

```
    //stairs[0]->stairs[1]->stairs[3]->stairs[2]->End
```

```
Ex: isClimbable({4, 0, 0, 1, 2, 1, 1, 0}, 8) == false
```

7. Implement the function `sumOfDigits` recursively. The function should return the sum of all of the digits in a *positive* integer.

```
int sumOfDigits(int num);

sumOfDigits(176); // should return 14
sumOfDigits(111111); // should return 6
```

8. Implement the function `isPalindrome` recursively. The function should return whether the given string is a palindrome. A palindrome is described as a word, phrase or sequence of characters that reads the same forward and backwards.

```
bool isPalindrome(string foo);

isPalindrome("kayak"); // true
isPalindrome("stanley yelnats"); // true
isPalindrome("LAs rock"); // false (but the sentiment is true
:))
```

9. Write the following linked list functions recursively.

```
// inserts a value in a sorted list, returns a head to new list
// before: head → 1 → 3 → 5 → 7 → 15
// insertInOrder(head, 8);
// after: head → 1 → 3 → 5 → 7 → 8 → 15
Node* insertInOrder(Node* head, int value);

// deletes all instances of value in a linked list, returns
list
// head
Node* deleteAll(Node* head, int value);

// prints the values of a linked list backwards
// head → 0 → 2 → 1 → 4 → 1 → 7
// reversePrint(head) will output 7 1 4 1 2 0
void reversePrint(Node* head);
```

10. Write a recursive function `isPrime` to determine whether a given integer input is a prime number or not.

Example:

isPrime(11) → true

isPrime(4) → false

```
bool isPrime(int num) {  
    // Fill in code here  
}
```

11. Write a recursive function to reverse a doubly linked list. Assume the linked list has all its functions implemented. The integer value in each node must not be changed (but of course the pointers can be).

Example:

Original:

After:

```
// Struct for Node that linked list is made from  
struct Node {  
    int val;  
    Node* next, prev;  
};
```

```
// Recursively reverse the doubly linked list and return the  
new  
// head.  
Node* reverse(Node* head) {  
    // Fill in code here  
}
```

12. Implement the following recursive function:

```
string longestCommonSubsequence(string s1, string s2);
```

The function should return the longest common subsequence of characters between the two strings s1 and s2. Basically, it should return a string of

characters that are common to both strings and are in the same order in both strings. Example:

```
string res = longestCommonSubsequence("smallberg",
    "nachenberg");

//res should contain "aberg" as seen in the green chars

res = longestCommonSubsequence("los angeles", "computers");

//res should contain the string "oes"
```

13. Implement a recursive function that merges two sorted linked lists into a single sorted linked list. The lists are singly linked; the last node in a list has a null next pointer. The function should return the head of the merged linked list. No new Nodes should be created while merging. Example:

```
List 1 = 1 -> 4 -> 6 -> 8
List 2 = 3 -> 9 -> 10
After merge: 1 -> 3 -> 4 -> 6 -> 8 -> 9 -> 10
```

Use the following definition of a Node of a linked list:

```
struct Node {
    int val;
    Node* next;
};
```

Use the following function header to get started:

```
Node* merge(Node* l1, Node* l2);
```

14. Rewrite the following function recursively. You can add new parameters and completely change the function implementation, but you can't use loops.

This function sums the numbers of an array from right to left until the sum exceeds some threshold. At that point, the function returns the running sum. Returns -1 if the threshold is not exceeded before the end of the array is reached.

```
int sumOverThreshold(int x[], int length, int threshold) {
    int sum = 0;
    for(int i = 0; i < length; i++) {
```

```

        sum += x[i];
        if (sum > threshold) {
            return sum;
        }
    }

    return -1;
}

```

15. Given the following program, give the output of each function call for parts a, b, and c.

```

void fizzbuzz(int x){
    if (x == 0) {
        cout << "fizzbuzz" << endl;
        return;
    }

    cout << "fizz" << endl;
    fizzbuzz(x-1);
    fizzbuzz(x-1);
}

```

- a. fizzbuzz(1)
- b. fizzbuzz(2)
- c. fizzbuzz(3)
